## Abstract

Sentiment analysis of product reviews on e-commerce platforms aids in determining the preferences of customers. Aspect-based sentiment analysis (ABSA) assists in identifying the contributing aspects and their corresponding polarity, thereby allowing for a more detailed analysis of the customer's inclination toward product aspects. This analysis helps in the transition from the traditional rating-based recommendation process to an improved aspectbased process. To automate ABSA, a labelled dataset is required to train a supervised machine learning model. As the availability of such dataset is limited due to the involvement of human efforts, an annotated dataset has been provided here for performing ABSA on customer reviews of mobile phones. The dataset comprising of product reviews of Apple-iPhone11 has been manually annotated with predefined aspect categories and aspect sentiments. The dataset's accuracy has been validated using state-of-the-art machine learning techniques such as Naïve Bayes, Support Vector Machine, Logistic Regression, Random Forest, K-Nearest Neighbor and Multi Layer

*Journal of Web Engineering, Vol. 21\_2,* 145–178. doi: 10.13052/jwe1540-9589.2122 © 2021 River Publishers

Perceptron, a sequential model built with Keras API. The MLP model built through Keras Sequential API for classifying review text into aspect categories produced the most accurate result with 67.45 percent accuracy. K-nearest neighbor performed the worst with only 49.92 percent accuracy. The Support Vector Machine had the highest accuracy for classifying review text into aspect sentiments with an accuracy of 79.46 percent. The model built with Keras API had the lowest 76.30 percent accuracy. The contribution is beneficial as a benchmark dataset for ABSA of mobile phone reviews.

**Keywords:** Aspect based sentiment analysis, customer reviews, ecommerce; labelled dataset, machine learning, recommendation system, supervised learning.

# 1 Introduction

Customer feedback in the form of user reviews provides an account of a user's hands-on experience with a product. Many e-commerce users rely on and trust these reviews more than other forms of advertising when making a purchase decision [1]. It has become obvious to analyse people's opinions since the rise of social media [2]. In an online survey conducted by the authors, 70.3 percent of the 202 survey respondents considered a product review before purchasing it. This indicates the importance of product reviews in today's world. Not only users, but stakeholders such as competing brands, can also learn the true intent of the customer from these reviews, which is useful in developing strategies to convert a potential customer into an actual customer. Sentiment analysis (SA) (also known as opinion mining) is a data mining field that can assist in understanding the user's experience and categorising it as positive, neutral, or negative [3, 4]. SA's focus has shifted from detecting the polarity of an entire document, paragraph, or sentence to the product aspects [5]. The idea behind aspect-based sentiment analysis (ABSA) is to identify the polarity of an aspect in a review sentence [6]. This type of sentiment analysis is a finer-grained version of previous versions such as document level and sentence level sentiment analysis [1]. Product reviews convey the users' overall sentiment for a product and reveal their sentiment for product features such as processor, battery, accessory, etc. The following steps mark the ABSA process [7]:

- 1. Identification of aspect terms from sentences
- 2. Determination of polarity of aspect terms

- 3. Detection of aspect categories
- 4. Determination of polarity of aspect categories

ABSA consists primarily of two tasks: the first is to identify the aspects of the reviewed product, and the second is to unearth the sentiment expressed by the user for these aspects. In 2014, the first ABSA task was performed for restaurant and laptop reviews in the English language at the Semantic Evaluation (SemEval) workshop on NLP. In its annotation process apart from categories and polarity of aspects, aspect terms were also tagged. Annotation process usually involves assigning of aspect categories and polarity labels manually [8]. In 2015, the SemEval task tagged aspect polarity values and aspect categories as a combination of entity and attribute. In 2016, as part of SemEval task, datasets for multiple languages were created. The entities for which ABSA has been performed are movie reviews, digital cameras, restaurants, telecommunications, consumer electronics, and museum [3] in a variety of languages such as Czech, Bangla [1], French and Hindi [5]. However, no labeled dataset exist in the literature for the mobile phone domain in the English language. As the growth of labeled datasets is dependent on human intervention, it is critical to contribute annotated datasets [9]. Tagging aspect categories entails identifying an aspect category and assigning it to a review sentence. For example, "The iPhone design is good and the camera quality is awesome" has two aspect categories: Mobile Design and Camera Quality. The polarity label for both of these categories will be positive in this example.

An annotated dataset has been created for performing aspect-based sentiment analysis of mobile phone reviews provided by Amazon's customers in the English language. The phone under consideration is Apple's iPhone11. Labelled dataset is required for execution of supervised machine learning algorithms. The contribution of the paper is a dataset of mobile phone reviews from Amazon India which has been manually tagged for aspect categories and aspect sentiments by a team of 6 people including the authors. The prepared dataset is novel as no other dataset for performing supervised machine learning for aspect based sentiment analysis of mobile phone reviews in English language was available. Also, preparation of such kind of dataset requires human effort leading to a declined growth of such datasets making it all the more important for contributing annotated datasets. This dataset can be used in the area of recommender systems to understand the mindset of customers towards the aspects of mobile phone [10]. 960 user reviews of the black-colored 64GB variant have been downloaded through Python.

These user comments have been collected in an excel file using Python's BeautifulSoup package that traverses the HTML parse tree to access web page elements. Once collected, the reviews have been divided into sentences, resulting in a total of 2109 review sentences. The resulting dataset's accuracy has been validated using state-of-the-art machine learning techniques. The goals are as follows:

- To build a labeled dataset of mobile phone reviews in English language by Amazon customers for automated ABSA.
- To conduct experiments so as to validate the effectiveness of the prepared dataset through machine learning models.

The remainder of the article is organized as follows: Section 2 consists of related work existing in literature. Section 3 describes the data collection process as well as the underlying survey that supported the dataset. Section 4 discusses the experimental evaluation and the results obtained. Lastly, Section 5 concludes the article.

## 2 Related Work

Classification is the process of identifying a class, distinguishing it from other classes, and finally assigning it to an object. In this process, objects are assigned to predefined classes. Text classification is the process of categorizing textual data, which can take the form of documents, paragraphs, sentences, or phrases [11, 12]. Sentiment analysis of textual data involves categorizing the data based on whether it contains positive, negative, or neutral opinions. Aspect-based sentiment analysis is a fine-grained version of sentiment analysis in which these opinions are assigned based on the product's aspects. This aggregate result of aspects and their polarities can then be used to learn the finer details of existing features and their goodness, which is more helpful than the product's overall opinion. E-commerce and other companies can also use this data to improve the quality of their products. Google Play Store, for example, uses reviews to rate the individual features of applications [2].

At SemEval 2014, the dataset for laptops and restaurants that included the aspect term, the polarity of the aspect term, the aspect category, and the polarity of the aspect category for each review was generated [3]. Aspect category was defined as a combination of entity type and its attribute type in a dataset created as part of SemEval 2015 [13]. As part of SemEval 2016, multilingual datasets were created for the restaurant (English, French, Spanish, Turkish, Russian, and Dutch language), laptop (English), mobile phone (Chinese, Dutch), digital camera (Chinese), hotel (Arabic), museum, and telecom (Turkish) domain [14]. A book-review dataset in Arabic with 14 aspect categories and 4 polarities (including the polarity 'conflict') was provided [15]. In [16], IT product- review dataset was provided for the ABSA task. Machine learning (linear-chain conditional random fields (CRFs)) approach was used to identify aspect terms and rule based approach supplemented this process.

When a machine is trained to predict the output given the input text to be classified and the output label or aspect categories/sentiments, this is referred to as supervised learning [11, 17–20]. The goal was to use deep learning and machine learning methods to determine the aspect category and sentiment of the collected review texts. The following are the various supervised machine learning techniques used:

#### K nearest neighbor (KNN)

KNN is an abbreviation for k-nearest neighbor, a statistical classification method. It is a nonparametric classifier from the family of proximity-based algorithms [9, 12, 21]. In this method, the nearest neighbors of the labeled examples from the training review are ranked for each test review, and then a class assignment is derived using the categories of the highest-ranked neighbors [22]. This model does not learn; instead, it memorizes and represents the entire dataset [23]. For high dimensional and sparse data, distance computation for the similarity between test and training reviews is computationally expensive. The most commonly used distance measures in this method are:

1. *Euclidean distance*: Euclidean distance between two points X and Y is determined as square root of sum of sum of their squared differences across all input attributes *i* [23]:

Euclidean distance
$$(X,Y) = \sqrt{\sum_{i=1}^{n} (x_i - y_i)^2}$$
 (1)

2. *Manhattan distance*: Sum of absolute difference of two points gives the Manhattan distance between two points.

Manhattan distance
$$(X, Y) = \sum_{i=1}^{n} |x_i - y_i|$$
 (2)

3. *Minkowski distance*: Generalization of above two distances gives the Minkowski distance.

Minkowski distance
$$(X,Y) = \left(\sum_{i=1}^{n} |x_i - y_i|^p\right)^{\frac{1}{p}}$$
 (3)

where, value of p is either 1 or 2. Manhattan distance is obtained when i is equal to 1 and Euclidean distance is obtained when p is equal to 2.

As a non-parametric method, this method suffers from the curse of dimensionality, requiring a large number of training examples to generalise satisfactorily for more features. Overfitting is more likely when large amounts of training data are provided in this manner. As a result, it is preferred for short texts rather than long texts [24].

#### Logistic Regression (LR)

In this method, given the input vector, the output class is assigned a probability [23, 25, 26]. The Logistic Regression model is based on the logistic function or sigmoid function. An S-shaped curve maps real values to values between 0 and 1. The standard notation for the sigmoid function is:

$$\frac{1}{1+e^{-z}}\tag{4}$$

Where, z is any real number to be transformed between 0 and 1. Logistic regression is a multi-class classification problem that began as a binary classification problem. For an input sample z, the probability of being in the first class is given as:

$$p(x) = \frac{e^{\beta^T \cdot z}}{1 + e^{\beta^T \cdot z}} \tag{5}$$

Where,  $\beta$  is parameter vector and z is the training sample. During training, algorithms such as maximum-likelihood estimation are used to minimize errors in the predicted probability.

#### Naïve Bayes (NB)

Naïve Bayes is a generative probabilistic classifier that makes use of the properties of the Bayes theorem to hypothesize the relationship between independent variables. The training documents estimate the conditional probability P(d|c) of a document belonging to a class, and the test documents

estimate P(c|d) using the Bayes theorem.

$$P(c|d) = \frac{P(c)P(d|c)}{P(d)}$$
(6)

It works well for independent features, which is also the method's underlying naive assumption. Due to the inherent regularisation, NB is less likely to overfit than discriminative classifiers and performs well for smaller samples. This method is incapable of modeling feature interaction. NB classifiers have three types: Bernoulli, Gaussian, and Multinomial. Gaussian is used for continuous datasets, Bernoulli is used for binary datasets, and Multinomial Nave Bayes is used for count datasets [12, 27]. This classifier is used when memory and processing are important factors [17].

## **Random Forest (RF)**

It is a discriminative classifier [12] based on multiple decision trees. A decision tree is made up of nodes and edges, where nodes represent the value of an attribute and edges represent the result of a test [28]. The best feature is chosen for splitting the node in the forest. For classification, the test is started at the root node and the edges are followed based on the results; the process is repeated until the leaf node is reached, and finally, the outcome corresponding to the leaf is predicted [29].

#### Support Vector Machine (SVM)

This is a discriminative classifier that attempts to identify a decision boundary by transforming non-linearly separable data to a higher dimension space with a separating hyperplane. The hyperplane can be represented as:

$$w \cdot x + b = 0 \tag{7}$$

Where w is the weight and b is the bias or the intercept. Each input point representing the sample lies on either side of the hyperplane. Initially designed for solving two-class problems, the decision surface separates the data points in the best manner with a maximum possible margin between the two classes. The data points which contribute to defining the margin are called support vectors. The magnitude of margin is the perpendicular distance from the hyperplane to the data points. The goal of training in SVM is to find the coefficients that separate the classes optimally.

$$y_i(w \cdot x_i + b) - 1 \ge 0 \ \forall i \tag{8}$$

## Deep Learning (DL)

Deep learning is a branch of machine learning that was inspired by neural networks. Deep learning models, as opposed to machine learning, learn the problem's features on their own without requiring it to go through a feature extraction process [25]. Layers are stacked on top of one another in the Sequential model one at a time until we achieve the desired architecture for Multilayer Perceptron [30]. The first step is to provide the input features to the input layer, after which the number of layers, the number of neurons in each layer, and the activation function are determined. The following step is to compile the model for training. Training the model entails determining the best weight parameter values to map our input to the output over several iterations known as epochs. The loss function for weight evaluation must be specified in this step. The batch size corresponds to the number of training samples to be considered within an epoch before the weight variables are updated, can also be specified.

## Multi Layer Perceptron (MLP)

The Perceptron was first introduced as a model of the biological neuron for binary classification [23]. It has been generalized to deal with multiclass problems. In Perceptron, the input is mathematically transformed by multiplying the input by the weight parameter, summing the weighted inputs, adding the bias variable, and passing it to an activation function, which produces the final output [31]. The binary classification activation function is defined as follows:

$$\Phi(z) = \{1 \text{ if } z \ge \theta, -1 \text{ otherwise}$$

$$(9)$$

where, *z* is the net input defined as:

$$z = w_1 x_1 + w_2 x_2 + \dots + w_n x_n \tag{10}$$

where, x is a sample from the training set, w is the corresponding weight vector and  $\theta$  is threshold.

The algorithm begins by initializing the weight vectors with zero. The corresponding predicted class for each sample is computed and compared to the actual class value. If the predicted and actual class values differ, the weights are updated. The updated weight vector is as follows:

$$\overline{w_j} = w_j + \eta (y^i - \overline{y^i}) x_j^i \tag{11}$$

where,  $\eta$  is the learning rate,  $y^i$  represents the actual class and  $\overline{y^i}$  represents the predicted class for sample  $x^i$ . Several layers guide classification in a Multi-layer Perceptron network [28]. It is termed as a logistic regression classifier variant [25]. It is a subtype of the feed-forward artificial neural network where the features of the input data are transformed into a predefined number of linearly separable spaces, with each layer fully connected.

## **3 Dataset Description**

The dataset constructed for ABSA consists of product reviews of the AppleiPhone11 mobile written by Amazon customers in the English language. A survey of 21 questions and 202 respondents conducted by the authors was used to scrap the dataset comprising of 960 product reviews. The online survey was conducted to understand the users' preference for usage of ecommerce platform for purchasing products online, consideration of product reviews in making their decision to purchase/reject a product, preference towards the brand and aspects/features of a mobile phone and their inclination for the operating system of a mobile phone.

The survey questions have been included in the appendix below. Apart from questions about the survey's objective, the survey included questions about user demographic information such as age, gender, profession, and education level. The questionnaire responses assisted us in justifying our dataset preparation. 18.3 percent of respondents were between the ages of 16 and 20, 45 percent of respondents were between the ages of 21 and 25, 19.8 percent of respondents were between the ages of 26 and 30, 5.4 percent of respondents were between the ages of 31 and 35, and 7.9 percent of respondents were between the ages of 36 and 40. The remaining respondents belonged to the remaining age groups, as shown in Figures 1 and 2. It should be noted that there is no relationship between the questionnaire respondents and the product reviewers under consideration. The responses were collected using Google forms, and the reviews were obtained from the Amazon India website.

From the total responses received, 61.9% were female respondents and 35.6% were male respondents.

The majority of respondents (67.3 percent) were students, with only 16.3 percent working and 2 percent running their businesses. The majority of respondents (31.2 percent) owned a Redmi phone, followed by Samsung (15.3%), OnePlus (11.9%), and Apple (11.4 percent). Approximately 65.9 percent of respondents have been using their current mobile phones for the

Figure 1 Responses to age group.

Figure 2 Responses to gender.

past two years, while only 6.4 percent have been using it for more than four years. The majority of respondents (53%) were satisfied with their current mobile phones, and 81.2 percent thought Android was a better operating system in a mobile phone. From the total responses recorded, 61.9% were female respondents and 35.6% were male respondents.

29.2 percent of all respondents voted for Amazon's e-commerce platform as a better place to buy a mobile phone. Another 29.2 percent of respondents thought that offline stores were a better option. Furthermore, Amazon and Flipkart received 25.7 percent of the responses. However, as shown in Figure 4, Flipkart received only 11.4 percent of the responses.

Most importantly, as illustrated in Figure 5, 70.3 percent of respondents considered a product's review before purchasing a product from e-commerce

Figure 3 Responses to important aspect of mobile phone.

Figure 4 Responses to preference for e-commerce platform.

platforms, and only 23.5 percent provided the review after purchasing the product indicating the sparsity of data on user reviews.

As shown in Figure 6, when comparing user review and rating as to which one is more dependable, user review received 18.8 percent of the responses alone and user rating received only 5.9 percent of the responses.

Finally, 32.7 percent of respondents thought Apple had the best phone on the market right now, but only 11.4 percent of the total owned it, as shown in Figure 7. We chose Apple-iPhone11 reviews to prepare the dataset because the majority of the users thought Apple was the best phone manufacturer.

The dataset for ABSA of mobile phone reviews in the English language was created programmatically by scraping publicly available reviews from

Figure 5 Responses to consideration of product reviews before and after purchase.

Figure 6 Responses to dependability of user reviews vs user ratings.

Amazon's Indian e-commerce site of Apple-iPhone11. Following data collection, the dataset was annotated with a predefined set of aspect categories.

a. Data collection

The scraped dataset includes 960 mobile phone reviews (2542 sentences). For training and testing the ABSA system, the dataset was cleaned manually

Figure 7 Responses to best brand of phone.

Figure 8 Top ten commonly occurring words in reviews.

to remove review sentences with no semantics. As a result, a total of 2109 sentences have been manually annotated with relevant aspects/features and sentiment categories by annotators described in Table 3. Figure 8 depicts the ten most frequently occurring words in the scrapped dataset.

Each review has been broken down into sentences using a full stop as the sentence terminator programmatically. A common review ID has been assigned to all the sentences of a review. Sentences with fewer than three alphabets were eliminated. Because review sentences can have multiple aspects, such sentences have been repeated and different aspect categories have been tagged for each of them, as shown in Table 1.

	Table 1         Sample annotate	ed dataset	
S.No	Review Text	Aspect Sentiment	Aspect Category
1	28/09/19, but the thing I got started heating up	Negative	Performance
1	As it continued tried to return the product by	Nagativa	A magan
1	As it continued, thed to return the product by speaking to Amazon customer support but in	Negative	Amazon
	vain		
1	Contacted Applecare, just to be consoled that it's quite normal	Neutral	Brand
1	I was much elated to receive the iPhone 11 so	Positive	Delivery
1	It was handed over to the Apple ASP as the return window closed on 10/10/19 (what use it was for??) and diagnosed as having issues and has further been sent to Apple repair facility at	Negative	Brand
1	So I'm here w/out my first iPhone after using it(suffering for??) just a little over 2 weeks and the CREDIT GOES TO AMAZON !!	Negative	Amazon
	Bravo, keep it up Amazon		
1	Some body called me back to convey that only Apple will decide which one to take back	Negative	Amazon
1	Why is then Amazon took up the sacred duty of selling such an item which they can't exchange/ have no control ? The product developed new issues like proximity sensor malfunction and last but most importantly loosing mobile network every other minute(even had two software updates)	Negative	Amazon
1	Why is then Amazon took up the sacred duty of selling such an item which they can't exchange/ have no control ? The product developed new issues like proximity sensor malfunction and last but most importantly loosing mobile network every other minute(even had two software updates)	Negative	Hardware
1	Why is then Amazon took up the sacred duty of selling such an item which they can't exchange/ have no control ? The product developed new issues like proximity sensor malfunction and last but most importantly loosing mobile network every other minute(even had two software updates)	Negative	Software

(Continued)

S.No	Review Text	Aspect Sentiment	Aspect Category
1	May be my first negative review about the product & Amazon both	Negative	General
1	May be my first negative review about the product & Amazon both	Negative	Amazon
2	I grabbed this phone with HDFC 6K Instant Discount Offer at Just 64K (128 GB Variant)	Positive	Price
2	I recommend you to prefer using 18W charger	Neutral	Hardware
2	The phone comes with 5W charger which charge your phone slowly	Negative	Hardware
2	The phone is great but if you use "in the box" accessories like "EarPods with Lighting Connector", then you might feel a little pain in your ears	Negative	Hardware
2	You can also take pictures in wide angles and the image quality is awesome	Positive	Camera
2	The iPhone design is good and the camera quality is awesome	Positive	MobileLooks
2	The iPhone design is good and the camera quality is awesome	Positive	Camera
2	But the product is great and I'm just lovin it	Positive	General
2	Phone got delivered at 9am on 28th September (I pre-order it on 27th September at 3am in the morning), I got my phone before the delivery date with nice and secured packaging	Positive	Delivery
2	The overall look of the phone is premium and face unlocking is fast	Positive	MobileLooks
2	Well, I've never tried the iPhone before and I'm using this for the first time (Yes, I'm already using other apple products like MacBook Air & Pro)	Neutral	General

 Table 1
 Continued

As of now, interpretation of emoticons by the users has not been taken into consideration and emoticons have been removed when found. The dataset has been divided into 70:30 for training and testing. Table 2 displays the statistics for the scraped data. It lists the predefined aspect categories that were identified prior to the start of the manual tagging process.

#### b. Annotation Steps

Six annotators identified the aspect category from a predefined list of aspect categories and expressed their polarity (positive, neutral, or negative) toward

Table 2	Dataset	statistics		
		Polar	ity	
Aspect Categories	Positive	Neutral	Negative	Total
Accessory	14	4	49	67
Amazon (Service + Seller)	28	8	32	68

the identified aspect. A total of 15 potential aspect categories of a mobile phone were identified. For tagging, the dataset was divided equally among three annotators. In the event of a tagging conflict, the authors made the final decision. Table 3 displays information about the annotators of the dataset.

## **4** Baseline Experiments and Results

Based on supervised machine learning, models such as Naive Bayes (NB), Support Vector Machine (SVM), Logistic Regression (LG), Random Forest (RF), K Nearest Neighbor (KNN), and Deep Learning Model (Keras-MLP) using Keras Sequential Model API in Python were constructed to identify the best model for classifying the reviews. Aspects such as memory, mobile

Evaluating Annotated Dataset of Customer Reviews for Aspect 161

quality, dust resistance, and water resistance were discarded in the machine learning process due to significantly fewer reviews. By removing them from the training and testing datasets, the accuracy of all models improved significantly, depicting the application of our annotated dataset, namely the detection of aspect category and sentiment.

Accuracy (ACC) is defined as the proportion of correctly classified reviews divided by the total number of reviews. It is a widely used metric for assessing the performance of classification methods [9]. Higher accuracy is preferred. Table 4 shows the accuracy scores from the training and testing phases for classifying review sentences based on their aspect categories and sentiments. The best results are highlighted in bold and green, while the worst results are highlighted in bold and red. The result was obtained through 3fold cross-validation, and hyperparameter tuning was used to improve the accuracy of these models.

$$ACC = \frac{TP + TN}{(TP + TN + FP + FN)}$$
(12)

where, *TP* stands for True Positive, i.e. percentage of actually correctly classified reviews that are predicted classified correctly.

*FP* stands for False Positive, i.e. percentage of incorrectly classified reviews that are predicted correctly.

*FN* stands for False Negative i.e. percentage of incorrectly classified reviews that are predicted incorrectly.

*TN* stands for True Negative i.e. percentage of correctly classified reviews that are predicted incorrectly.

Table 5 shows the *precision* (P), *recall* (R) and *f-measure* (F1) for train and test data for the built models. The *precision*, *recall* and *f-measure* scores

Table 5	Evaluation	of machin	ne learning	nodels on proposed dataset				
	Te	sting Phas	se	Testing Phase				
	Asp	Aspect Category			ct Sentime	ent		
Model	Precision	Recall	F-Score	Precision	Recall	F-Score		
Keras-MLP	0.66	0.63	0.71	0.75	0.76	0.77		
KNN	0.56	0.5	0.45	0.76	0.77	0.75		
LR	0.63	0.63	0.62	0.74	0.77	0.75		
NB	0.56	0.57	0.56	0.75	0.79	0.77		
RF	0.63	0.63	0.6	0.75	0.78	0.73		
SVM	0.62	0.64	0.62	0.74	0.79	0.75		

obtained are calculated as:

$$Precision(P) = \frac{TP}{(TP + FP)}$$
(13)

$$Recall(R) = \frac{TP}{(TP + FN)}$$
(14)

*F-measure* combines both precision and recall as follows:

$$f\text{-measure} = 2 * \frac{\text{precision} * \text{recall}}{\text{precision} + \text{recall}}$$
(15)

As shown in Figures 9 and 10, the deep learning model (MLP model built using Keras API) for classifying review text into fifteen predefined aspect categories produced the most accurate result in the testing phase, with an accuracy of 67.45 percent. K-nearest neighbor performed the worst in this task, achieving only 49.92 percent accuracy. With an accuracy of 79.46 percent, Support Vector Machine was the most accurate for classifying review text into three predefined aspect sentiments. The MLP model had the lowest accuracy with 76.30 percent for aspect sentiment classification.

This experimental evaluation was conducted through the *Keras* module for deep learning and *the scikit-learn* module for machine learning models provided by open-source Python software [32–34]. Standard Windows system with 64 bit Intel Core i3 CPU @2.00 GHz, 2000 MHz, 2 Core(s), 4 logical processors and 4.00 GB RAM was used for training and testing the ABSA system.

For each of the above models standard architecture commonly followed was initially used. This architecture was then optimimum performance by tuning (trying out all possible combinations of hyperparameters to achieve the

Figure 9 Performance of models on proposed dataset (aspect category).

**Supervised Models** 

Figure 10 Performance of models on proposed dataset (aspect sentiment).

best possible output) the hyperparameters using the *GridSearchCV* method under *the scikit-learn* library in Python. The hyperparameters tuned for the stated machine learning models for aspect category and aspect sentiment classification are shown in Tables 6 and 7 below.

Tables 8 and 9 are supplementary tables that detail the performance of the Sequential model for aspect category and aspect sentiment classification over 50 epochs and batch size 100, respectively. The input features are limited

to a maximum of 2000 words and are fed into the sequential model via the *input\_dim* parameter. The chosen model is made up of two dense layers: the first layer is made up of 512 neurons, and the second layer is made up of 15 neurons, the output of which is mapped to 15 categories in the case of aspect

Figure 12 Sequential model accuracy and loss corresponding to aspect category classification.

Figure 13 Sequential model accuracy and loss corresponding to aspect sentiment classification.

category classification and three neurons in the case of aspect sentiment classification. Figure 11 depicts the architecture of the sequential model.

*ReLu* activation function is used in the first layer and *softmax* activation function in the output layer. A *dropout* of 0.5 is added to set the fraction of inputs to zero to reduce overfitting. The model is compiled using *categorical cross-entropy* loss and optimized with the stochastic gradient descent method known as the *adam* optimizer. A validation split of 10% is configured while fitting the model to check the model for training and validation accuracies over all the epochs.

Figures 12 and 13 represent the model accuracy and model loss of the sequential model for aspect category and aspect sentiment classification respectively.

As shown in Figure 12, the sequential model accuracy for testing phase for aspect sentiment classification is almost constant after 30 epochs and is about a point less than the training phase. Also, in Figure 13, the model loss testing phase for aspect sentiment classification is constant after 20 epochs.

## 5 Limitations and Conclusion

A dataset for ABSA of mobile phone reviews has been provided. The dataset has been designed to automate aspect category extraction and aspect category polarity identification using machine learning and deep learning techniques. Furthermore, the constructed dataset has been evaluated using several stateof-the-art machine learning techniques. Understanding the intent conveyed by emoticons was not taken into account in this study. In addition, the abbreviated words have not been addressed. The dataset collected for a single entity – Apple-iPhone11 mobile Phone – had less than 1000 reviews, resulting in a small corpus of the labeled dataset but significant results. The above-mentioned satisfactory results were generated using actual imbalanced data, which can be improved by balancing the dataset. The MLP sequential model was the most accurate when the number of predefined aspect categories were fifteen and the least accurate when the number of predefined aspect sentiments were three, indicating a need for more data for the training process. Traditional ML model Support Vector Machine performed the best when only three predefined aspect sentiments were to be classified. The majority of the ML models achieved satisfactory accuracies ranging from 49 to 67 percent for aspect category classification and 76 to 79 percent for aspect sentiment classification. As a result, this dataset of mobile phone reviews in English can serve as a benchmark for ABSA. The future scope of this work would be to calculate the importance of mobile phone aspects for customers and products to develop an aspect-based recommender system.

## **Author Contributions**

All authors contributed to this work. Conceptualization and method selection was done by Dimple Chehal, Parul Gupta and Payal Gulati; data collection and analysis was done by Dimple Chehal; writing – original draft preparation was done by Dimple Chehal; and writing – review and editing was done by Parul Gupta and Payal Gulati. All the authors have read, reviewed and approved the final manuscript.

# Acknowledgement

Dimple Chehal is thankful to University Grants Commission (UGC), New Delhi, India for providing fellowship under Junior Research Fellowship (JRF) vide letter no. F.15-9(JUNE 2015)/2015(NET) from August 2017 to July 2019 and Senior Research Fellowship (SRF) from August 2019 onwards.

30000-40000	$\bigcirc$
40000-50000	Ó
Above 50000	0

13. Which of the following payment mode do you prefer? \* *Mark only one oval.* 

Cash	$\bigcirc$
EMI using debit/credit card	$\bigcirc$
Payments using Wallets (PayTM/Amazon Pay/Bhim UPI etc)	$\bigcirc$

- 172 D. Chehal et al.
- 14. What are the three most important features for you in a mobile phone? \* *Check all that apply.*

Accessory	$\overline{\bigcirc}$
Battery	$\bigcirc$
Camera	$\bigcirc$
Processor	$\bigcirc$
Screen/Display	$\bigcirc$
Hardware	$\bigcirc$
Memory	$\bigcirc$
Mobile Design	$\bigcirc$
Operating System	$\bigcirc$
Price	$\bigcirc$
Software	$\bigcirc$
Warranty	$\bigcirc$
Dust resistance	$\bigcirc$
Water resistance	$\bigcirc$

15. Which e-commerce platform you feel is good for purchasing a mobile phone? \*

Mark only one oval.

Amazon	
	Q
Flipkart	$\bigcirc$
Both	$\bigcirc$
Neither	$\bigcirc$
Prefer buying from offline store	$\bigcirc$

16. Do you consider a product's review before buying it from any ecommerce platform? \*

Mark only one oval.

17. Do you provide a product review after you've bought it from any ecommerce platform? *Mark only one oval* 

18. What kind of experience you post in your reviews of a product?

Only the positive ones	$\overline{\bigcirc}$
Mostly the negative ones	$\bigcirc$
Critical reviews containing both positive and negative	$\bigcirc$

19. Which is more dependable when buying a product online? \* *Mark only one oval.* 

User Ratings	$\bigcirc$
User Reviews	0
Both	0
None	0
I don't know what they are	Õ

20. Which company you think has the best phone in market right now? \* *Mark only one oval.* 

Apple	0
Samsung	$\bigcirc$
Google	$\bigcirc$
Motorola	$\bigcirc$
Xioami	0
Realme	$\bigcirc$
Vivo	$\bigcirc$
Oppo	$\bigcirc$
Honor	$\bigcirc$
OnePlus	$\bigcirc$
Other	

21. Any suggestions/improvements for this survey?

## **Biography**

**Dimple Chehal** is a Ph.D. student at J.C. Bose University of Science & Technology, YMCA, Faridabad, India since August 2017. She is Senior Research Fellow (SRF) under University Grants Commission's (UGC), Ph.D. fellowship scheme. Dimple held the position of Systems Engineer at Tata Consultancy Services Private Ltd, India. Her Ph.D. work centers on review based recommender system in the e-commerce domain and current research interests include Data Mining, Natural Language Processing and Machine Learning.

**Parul Gupta** is an Associate Professor at Department of Computer Engineering, J.C. Bose University of Science & Technology, YMCA, Faridabad, India. She has teaching experience of over 17 years. In 2013, she received her Ph.D. from MDU Rohtak. She has published more than 25 research papers in reputed international journals and conferences. Her research interests include Data Mining, Information Retrieval, Databases and Sustainable Smart Cities.

**Payal Gulati** is an Assistant Professor at Department of Computer Engineering, J.C. Bose University of Science & Technology, YMCA, Faridabad, India. She received her Ph.D. in 2013 from Maharishi Dayanand University, Rohtak, India and has over 14 years of experience. She has contributed more than 30 papers in reputed journals and conferences. She is also a reviewer in Springer and Oxford journals. Her subject of interests includes Data Mining, Information Retrieval, Predictive Analysis, Energy Research and Sustainable Smart Cities.
